## US Food Demand

Institute for
New Economic Thinking
AT THE OXFORD MARTIN SCHOOL
US Food Demand (Expenditure) - Hendry and Mizon (2011):

US Food Demand (Expenditure) - Hendry and Mizon (2011):

- The data variables are (lower case denoting logs):
. $e_{f}$ is constant price, per capita, expenditure on food
. $e$ is constant price, per capita, total expenditure
. $p$ is deflator of total expenditure
. $y$ is constant price, per capita, income
- $p_{f}-p$ is real price of food
. $s=(y-e)$ is an approximation to the savings ratio
. $a$ is average family size-demographic effects
. n is total population of the USAshould be irrelevant as per capita data.

There are considerable changes over the period:

- $e_{f}$ and $e$ fall sharply at the beginning of the Great Depression, rise substantially till WWII, fall after, then resume a gentle rise,
- so $\Delta e_{f}$ is much more volatile pre WWII: $\Delta e$ has a similar but less pronounced pattern).
- $p_{f}-p$ is quite volatile till after WWII, then is relatively stable,
- s rises from 'forced saving' in WWII.
- a has fallen considerably, partly reflecting changes in social mores.

## Modelling Food Demand

- Tobin (1950) modelled US food demand: used time series 1912-48.
We use extended time-series data, updated by Reade (2008).
- The basic theory is:

$$
\begin{equation*}
e_{f}=f\left(e, p_{f}-p, s, a\right) \tag{1}
\end{equation*}
$$

- Conventional theory expects:

$$
\begin{equation*}
\frac{\partial e_{f}}{\partial e}>0, \quad \frac{\partial e_{f}}{\partial\left(p_{f}-p\right)}<0, \quad \frac{\partial e_{f}}{\partial a}<0, \quad \frac{\partial e_{f}}{\partial n}=0 \tag{2}
\end{equation*}
$$

## Static model

The static theory model estimates are:

$$
\begin{aligned}
e_{\mathrm{f}, \mathrm{t}} & =\underset{(4.02)}{5.30}+\underset{(0.14)}{0.77} \mathrm{e}_{\mathrm{t}}+\underset{(0.08)}{0.11}\left(\mathrm{p}_{\mathrm{f}}-\mathrm{p}\right)_{\mathrm{t}}+\underset{(0.14)}{0.72} \mathrm{~s}_{\mathrm{t}}-\underset{(0.23)}{0.36} a_{\mathrm{t}}-\underset{(0.22)}{0.73} n_{\mathrm{t}} \\
\mathrm{R}^{2} & =0.94 \chi_{\text {nd }}^{2}(2)=19.5^{* *} F_{\text {arch }}(1,72)=216.8^{* *} F_{\mathrm{ar}}(2,66)=44.3^{* *} \\
\widehat{\sigma} & =0.055 \mathrm{~F}_{\text {reset }}(2,66)=18.1^{* *} \mathrm{~F}_{\text {het }}(10,63)=23.2^{* *}
\end{aligned}
$$

- The static economic-theory model has a very poor fit, and does not adequately capture behaviour of observed data.
- The price elasticity $\left(p_{f}-p\right)_{t}$ has the 'wrong sign', contradicting (2), but is insignificant.
- Although it is theoretically irrelevant, population $n_{t}$ is significant.
- Finally, every mis-specification test strongly rejects. Next Figure shows the estimated model fails to describe the 1930s.

## Static Model

OXFORD

- Magnus and Morgan (1999) ('competition'):

Most contributors found dynamic models were non-constant over full sample 1931-1989, so modelled post 1950 only.

- Magnus and Morgan (1999) ('competition'):

Most contributors found dynamic models were non-constant over full sample 1931-1989, so modelled post 1950 only.

- Hendry (1999):
i) Added Indicators for inter-war \& post-war
- Food program, Great Depression
ii) Reversed procedure: indicators for all observations from 1950s onwards
- 1970s
- Retained significant and re-select.
- Magnus and Morgan (1999) ('competition'):

Most contributors found dynamic models were non-constant over full sample 1931-1989, so modelled post 1950 only.

- Hendry (1999):
i) Added Indicators for inter-war \& post-war
- Food program, Great Depression
ii) Reversed procedure: indicators for all observations from 1950s onwards
- 1970s
- Retained significant and re-select.
- Hendry (1999) found a constant equation over 1931-1989 by adding impulse indicators pre-1950 for large outliers, identified as being due to a food program and post-war de-rationing.

## Food Expenditure with Impulses

$$
\begin{aligned}
& \Delta e_{f}=\underset{(0.035)}{0.13} \Delta e_{f, t-1}-\underset{(0.012)}{0.11} I_{31}-\underset{(0.012)}{0.11} I_{32} \\
& +\underset{(0.0096)}{0.028} \mathrm{I}_{34}-\underset{(0.0096)}{0.027} \mathrm{I}_{43}+\underset{(0.0085)}{0.031} \mathrm{I}_{70} \\
& +\underset{(0.04)}{0.59} \Delta e_{\mathrm{t}}-\underset{(0.031)}{0.32 \Delta\left(p_{f}-p\right)_{t}-\underset{(0.1)}{0.19} \Delta n_{t}} \\
& +\underset{(0.035)}{0.23} \Delta \mathrm{~s}_{\mathrm{t}}-\underset{(0.023)}{0.36} \mathrm{ECM}_{\mathrm{t}-1} \\
& F_{\text {ar }}(2,59)=0.68 \chi_{\text {nd }}^{2}(2)=1.78 \quad F_{\text {arch }}(1,70)=0.27 \\
& F_{\text {reset }}(2,59)=0.23 F_{\text {het }}(12,54)=1.01
\end{aligned}
$$

Solved cointegrating relation with dummies excluded:

$$
E C M=e_{f}-\underset{(0.01)}{0.63} \mathrm{e}+\underset{(0.04)}{0.13}\left(p_{\mathrm{f}}-p\right)-\underset{(0.08)}{1.12} \mathrm{~s}+\underset{(0.01)}{0.45} \mathrm{n}
$$

Adding indicators for every observation?
David Hendry trying to convince Søren Johansen at Engle and Granger Nobel award ceremony 2003 Stockholm:

## Motivation

Unknown unknowns: unknown number of location shifts/outliers of unknown magnitudes at unknown times.

- Testing model mis-specification
- Learning from data
- Testing super exogeneity

## Unmodelled location shifts have pernicious effects:

- in sample, mis-specified empirical models, distorting inference;
- out of sample, assess forecast failure.

December 2014 - January $2015 \quad 15.1 .2015$

Numbers and magnitudes of breaks in models usually unknown: obviously unknown for unknowingly omitted variables.
General approach required to detect location shifts anywhere in sample while also selecting over many candidate variables.

Theory-embedding in general model allowing for outlier/location shift at any point in time.

## Detecting multiple breaks

Numbers and magnitudes of breaks in models usually unknown: obviously unknown for unknowingly omitted variables.
General approach required to detect location shifts anywhere in sample while also selecting over many candidate variables.

Theory-embedding in general model allowing for outlier/location shift at any point in time.

Impulse-Indicator Saturation (IIS) creates complete set of indicator variables: $\left\{1_{\{j=\mathrm{t}\}}\right\}=1$ when $\mathrm{j}=\mathrm{t}$ and 0 otherwise for $\mathrm{j}=1, \ldots, \mathrm{~T}$ :

$$
\left[\begin{array}{llll}
1 & 0 & 0 & 0  \tag{3}\\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & \ddots
\end{array}\right]
$$

add T impulse indicators to set of candidate variables when T obs.

Hendry, Johansen, and Santos (2008): impulse-indicator saturation (IIS): adding an indicator dummy variable for each observation to candidate set of variables for the model.

$$
\begin{equation*}
y_{t}=\alpha_{0}+\alpha_{1} I_{1}+\alpha_{2} I_{2}+\ldots+\alpha_{T} I_{T}+u_{t} \tag{4}
\end{equation*}
$$

This has $\mathrm{T}+1$ parameters for T observations.
However, the impulses can be added in blocks (say $T=100$ ):
(1) Partition in 2 blocks, $\mathrm{B}_{1}=\mathrm{I}_{1}, \ldots, \mathrm{I}_{50}, \mathrm{~B}_{2}=\mathrm{I}_{51}, \ldots, \mathrm{I}_{100}$,
C.f. estimating models over two subsamples of $\mathrm{T} / 2$.
(2) Run model selection on each block, form union $S$,
(3) Run model selection on $S$.

Consider $y_{t} \sim \operatorname{IID}\left[\mu, \sigma_{\epsilon}^{2}\right]$ for $t=1, \ldots, T$

- First, include half of indicators, record significant: just 'dummying out' $\mathrm{T} / 2$ observations for estimating $\mu$
- Then omit, include other half, record again.
- Combine sub-sample indicators, \& select significant.
$\alpha \mathrm{T}$ indicators selected on average at significance level $\alpha$
Feasible 'split-sample' (IIS) algorithm: see Hendry, Johansen, and Santos (2008)
Many well-known procedures are variants of IIS.
- Chow (1960) test is sub-sample IIS over T $-k+1$ to $T$ without selection.
- Salkever (1976) tests parameter constancy by indicators.
- Recursive estimation equivalent to IIS over future sample, reducing indicators one at a time.

Next Figure illustrates 'split-half' approach for $y_{t} \sim \operatorname{IN}\left[\mu, \sigma_{y}^{2}\right]$
Three rows correspond to the three stages:

- first half of the indicators, second half, then selected indicators combined.

Three columns report:

- indicators entered,
- indicators retained,
- and fitted and actual values of selected model.

Many indicators added, but only one is retained in row 1.
When second half entered (row 2), none is retained.
Combined retained dummies entered (here just one), and selection again retains it.

## Null 'split-sample' search in IIS

Selected model: actual and fitted

## Null 'split-sample' search in IIS

## Null 'split-sample' search in IIS

Consider adding first half of the indicators:

$$
\begin{equation*}
y_{t}=\mu_{1}+\sum_{j=1}^{T / 2} \delta_{j} d_{j, t}+\varepsilon_{t} \tag{5}
\end{equation*}
$$

Consider adding first half of the indicators:

$$
\begin{equation*}
y_{t}=\mu_{1}+\sum_{j=1}^{T / 2} \delta_{j} d_{j, t}+\varepsilon_{t} \tag{5}
\end{equation*}
$$

The estimators are:

$$
\begin{align*}
& \widehat{\mu}_{1}=\frac{1}{\mathrm{~T} / 2} \sum_{\mathrm{t}=\mathrm{T} / 2+1}^{\mathrm{T}} y_{\mathrm{t}},  \tag{6}\\
& \mathrm{~s}_{1}^{2}=\frac{1}{\mathrm{~T} / 2-1} \sum_{\mathrm{t}=\mathrm{T} / 2+1}^{\mathrm{T}}\left(y_{\mathrm{t}}-\widehat{\mu}_{1}\right)^{2}  \tag{7}\\
& \widehat{\delta}_{\mathrm{t}}=y_{\mathrm{t}}-\widehat{\mu}_{1}, \quad \mathrm{t}=1, \ldots, \mathrm{~T} / 2 \tag{8}
\end{align*}
$$

Consider adding first half of the indicators:

$$
\begin{equation*}
y_{t}=\mu_{1}+\sum_{j=1}^{T / 2} \delta_{j} d_{j, t}+\varepsilon_{t} \tag{5}
\end{equation*}
$$

The estimators are:

$$
\begin{align*}
& \widehat{\mu}_{1}=\frac{1}{\mathrm{~T} / 2} \sum_{\mathrm{t}=\mathrm{T} / 2+1}^{\mathrm{T}} y_{\mathrm{t}},  \tag{6}\\
& \mathrm{~s}_{1}^{2}=\frac{1}{\mathrm{~T} / 2-1} \sum_{\mathrm{t}=\mathrm{T} / 2+1}^{\mathrm{T}}\left(y_{\mathrm{t}}-\widehat{\mu}_{1}\right)^{2}  \tag{7}\\
& \widehat{\delta}_{\mathrm{t}}=y_{\mathrm{t}}-\widehat{\mu}_{1}, \mathrm{t}=1, \ldots, \mathrm{~T} / 2 \tag{8}
\end{align*}
$$

so that residuals are:

$$
\begin{aligned}
\widehat{\varepsilon}_{\mathrm{t}} & =0, \mathrm{t}=1, \ldots, \mathrm{~T} / 2 \\
\widehat{\varepsilon}_{\mathrm{t}} & =\mathrm{y}_{\mathrm{t}}-\widehat{\mu}_{1}, \quad \mathrm{i}=\mathrm{T} / 2+1, \ldots, \mathrm{~T}
\end{aligned}
$$

## Split-Half Estimators

The final estimates are:

$$
\begin{equation*}
\tilde{\mu}=\frac{\sum_{t=1}^{\mathrm{T}_{1}} y_{\mathrm{t}} 1_{\left\{\left|\mathrm{t}_{1, \delta_{\mathrm{t}}}\right|<c_{\alpha}\right\}}+\sum_{\mathrm{t}=\mathrm{T}_{1}+1}^{\mathrm{T}} y_{\mathrm{t}} 1_{\left\{\left|\mathrm{t}_{2, \delta_{\mathrm{t}}}\right|<c_{\alpha}\right\}}}{\sum_{\mathrm{t}=1}^{\mathrm{T}_{1}} 1_{\left\{\left|\mathrm{t}_{1, \hat{\delta}_{\mathrm{t}}}\right|<c_{\alpha}\right\}}+\sum_{\mathrm{t}=\mathrm{T}_{1}+1}^{\mathrm{T}} 1_{\left\{\left|\mathrm{t}_{2, \hat{\delta}_{\mathrm{t}}}\right|<c_{\alpha}\right\}}} \tag{9}
\end{equation*}
$$

and
$\tilde{\sigma}_{\varepsilon}^{2}=\frac{\sum_{t=1}^{\mathrm{T}_{1}}\left(\mathrm{y}_{\mathrm{t}}-\widehat{\mu}_{1}\right)^{2} 1_{\left\{\left|\mathrm{t}_{1, \delta_{\mathrm{t}}}\right|<\mathrm{c}_{\alpha}\right\}}+\sum_{\mathrm{t}=\mathrm{T}_{1}+1}^{\mathrm{T}}\left(\mathrm{y}_{\mathrm{t}}-\widehat{\mu}_{2}\right)^{2} 1_{\left\{\left|\mathrm{t}_{2, \hat{\delta}_{\mathrm{t}}}\right|<c_{\alpha}\right\}}}{\sum_{\mathrm{t}=1}^{\mathrm{T}} 1_{\left\{\left|\mathrm{t}_{1, \hat{\delta}_{\mathrm{t}}}\right|<\mathrm{c}_{\alpha}\right\}}+\sum_{\mathrm{t}=\mathrm{T}_{1}+1}^{\mathrm{T}} 1_{\left\{\left|\mathrm{t}_{2, \hat{\delta}_{\mathrm{t}}}\right|<\mathrm{c}_{\alpha}\right\}}-1}$.

## Properties of IIS

Let $y_{t}=\mu+\sigma_{\varepsilon} \varepsilon_{\mathrm{t}}, \mathrm{t}=1, \ldots$, T be i.i.d., where $\varepsilon_{\mathrm{t}}$ has symmetric continuous density $f($.$) with mean zero, variance one. Let T=T_{1}+T_{2}$ and assume that $\mathrm{T}_{1} / \mathrm{T} \rightarrow \lambda_{1}$ and $\mathrm{T}_{2} / \mathrm{T} \rightarrow \lambda_{2}$ where $0<\lambda_{1}, \lambda_{2}<1$, with $\lambda_{1}+\lambda_{2}=1$ then:

$$
\begin{equation*}
\mathrm{T}^{1 / 2}(\widetilde{\mu}-\mu) \xrightarrow{\mathrm{D}} \mathrm{~N}\left[0, \sigma_{\varepsilon}^{2} \sigma_{\mu}^{2}\right] \tag{7}
\end{equation*}
$$

where
$\sigma_{\mu}^{2}=\left(\int_{-c_{\alpha}}^{c_{\alpha}} f(\varepsilon) d \varepsilon\right)^{-2}\left[\int_{-c_{\alpha}}^{c_{\alpha}} \varepsilon^{2} f(\varepsilon) d \varepsilon\left(1+4 c_{\alpha} f\left(c_{\alpha}\right)\right)+\left(\frac{\lambda_{1}^{2}}{\lambda_{2}}+\frac{\lambda_{2}^{2}}{\lambda_{1}}\right)\left(2 c_{\alpha} f\left(c_{\alpha}\right)\right)^{2}\right]$
where:

$$
\int_{-c_{\alpha}}^{c_{\alpha}} f(\epsilon) d \epsilon=1-\alpha
$$

measures the impact of truncating the residuals.

## Split-Half Estimator

Using $\int_{-c_{\alpha}}^{c_{\alpha}} f(\varepsilon) \mathrm{d} \varepsilon=1-\alpha$, and for the normal distribution, $f(\varepsilon)=\phi(\varepsilon)$, using integration by parts we find:

$$
\int_{-c_{\alpha}}^{\mathrm{c}_{\alpha}} \varepsilon^{2} \phi(\varepsilon) \mathrm{d} \varepsilon=\int_{-\mathrm{c}_{\alpha}}^{\mathrm{c}_{\alpha}} \phi(\varepsilon) \mathrm{d} \varepsilon-2 \mathrm{c}_{\alpha} \phi\left(\mathrm{c}_{\alpha}\right)
$$

so that for $\lambda_{1}=\lambda_{2}=0.5$ (split-half) above simplifies to:

$$
\sigma_{\mu}^{2}=\frac{1}{(1-\alpha)}\left(1+4 c_{\alpha} \phi\left(c_{\alpha}\right)-\frac{2 c_{\alpha} \phi\left(c_{\alpha}\right)}{(1-\alpha)}\left[1+2 c_{\alpha} \phi\left(c_{\alpha}\right)\right]\right)
$$

where $\sigma_{\mu}^{2} \rightarrow 1$ as $\left|\mathrm{c}_{\alpha}\right| \rightarrow \infty$.

## Variance Estimator

$$
\begin{equation*}
\tilde{\sigma}_{\varepsilon}^{2}=\frac{\left.\sum_{i=1} T_{1}\left(y_{t}-\widehat{\mu}_{1}\right)^{2} 1_{\left\{\left|t_{1, \widehat{\delta}_{t}}\right|<c\right.}+\sum_{\alpha}+T_{1+1}\left(y_{t}-\widehat{\mu}_{2}\right)^{2} 1_{\left\{\left|t_{2, \widehat{\delta}_{t}}\right|<c\right.} T_{\alpha}\right\}}{\sum T_{1} 1_{\left\{\left|t_{1, \widehat{\delta}_{t}}\right|<c_{\alpha}\right\}}+\sum T=T_{1}+11_{\left\{\left|t_{2, \widehat{\delta}_{t}}\right|<c_{\alpha}\right\}}-1} \tag{11}
\end{equation*}
$$

The estimator $\widetilde{\sigma}_{\varepsilon}^{2}$, has the limit

$$
\widetilde{\sigma}_{\varepsilon}^{2} \xrightarrow{P} \sigma_{\varepsilon}^{2} \kappa=\mathrm{V}\left(\varepsilon \| \varepsilon \mid<\mathrm{c}_{\alpha}\right) .
$$

For the normal distribution, $\mathrm{f}(\varepsilon)=\phi(\varepsilon)$, we have the expression:

$$
\kappa=1-\frac{2 c_{\alpha} \phi\left(c_{\alpha}\right)}{1-\alpha}
$$

where $\mathrm{k} \rightarrow 1$ as $|\mathrm{c}| \rightarrow \infty$

## IIS under the null

## Effects of Impulse Indicator Saturation under null:

Selection effects on mean and variance estimators similar to 'trimming':

- Small loss in efficiency (consistency effect on variance estimate $\tilde{\sigma}_{\epsilon}$, efficiency effect through $\sigma_{\mu}^{2}$ )
- Controllable by choosing more conservative $\alpha$

IIS interpretable as robust estimator, but allows for joint selection over variables.

Johansen and Nielsen (2016) 'gauge' is consistent:

$$
\begin{align*}
& \hat{g}=\frac{1}{\mathrm{~T}} \sum_{\mathrm{t}=1}^{\mathrm{T}} 1_{\left(\left|y_{\mathrm{t}}-x_{\mathrm{t}} \tilde{\beta}\right|>\tilde{\sigma}_{\epsilon} c_{\alpha}\right)}  \tag{12}\\
& \mathrm{E}[\hat{\mathrm{~g}}] \rightarrow \mathrm{P}\left(\left|\epsilon_{1}\right|>\sigma c_{\alpha}\right)=\alpha \tag{13}
\end{align*}
$$

Johansen \& Nielsen (2009) \& (2016) extend IIS to both stationary and unit-root autoregressions:
When distribution is symmetric, adding T impulse-indicators to a regression with $n$ variables, coefficient $\beta$ (not selected) and second moment $\Sigma$ :

$$
\mathrm{T}^{1 / 2}(\widetilde{\boldsymbol{\beta}}-\underset{\sim}{\boldsymbol{\beta}}) \xrightarrow{\mathrm{D}} \mathrm{~N}_{\mathrm{n}}\left[\mathbf{0}, \sigma_{\epsilon}^{2} \boldsymbol{\Sigma}^{-1} \boldsymbol{\Omega}_{\beta}\right]
$$

Efficiency of IIS estimator $\widetilde{\boldsymbol{\beta}}$ with respect to OLS $\widehat{\boldsymbol{\beta}}$ measured by $\Omega_{\beta}$ depends on $\mathrm{c}_{\alpha}$ and distribution

Johansen \& Nielsen (2009) \& (2016) extend IIS to both stationary and unit-root autoregressions:
When distribution is symmetric, adding T impulse-indicators to a regression with n variables, coefficient $\beta$ (not selected) and second moment $\Sigma$ :

$$
\mathrm{T}^{1 / 2}(\widetilde{\boldsymbol{\beta}}-\boldsymbol{\beta}) \xrightarrow{\mathrm{D}} \mathrm{~N}_{\mathrm{n}}\left[\mathbf{0}, \sigma_{\epsilon}^{2} \boldsymbol{\Sigma}^{-1} \boldsymbol{\Omega}_{\beta}\right]
$$

Efficiency of IIS estimator $\widetilde{\boldsymbol{\beta}}$ with respect to OLS $\widehat{\boldsymbol{\beta}}$ measured by $\boldsymbol{\Omega}_{\beta}$ depends on $\mathrm{c}_{\alpha}$ and distribution
Must lose efficiency under null; small loss $\alpha$ T: 1 observation at $\alpha=1 / \mathrm{T}$ if $\mathrm{T}=100$, despite T extra candidates.
Potential for major gain under alternatives of breaks and/or data contamination: variant of robust estimation but can be done jointly with all other selections

## A single outlier

Single Outlier at $t=T_{1}$ :
DGP: $y_{t}=\lambda_{1} 1_{\left\{\mathrm{t}=\mathrm{T}_{1}\right\}}+\epsilon_{\mathrm{t}}$
matched by model: $y_{t}=\gamma d_{t=T_{1}}$

$$
\begin{aligned}
\left(\hat{\gamma}-\lambda_{1}\right) & =\left(d_{\mathrm{t}=\mathrm{T}_{1}}^{\prime} \mathrm{d}_{\mathrm{t}=\mathrm{T}_{1}}\right)^{-1} \mathrm{~d}_{\mathrm{t}=\mathrm{T}_{1}}^{\prime} \epsilon_{\mathrm{t}} \\
& =\epsilon_{\mathrm{T}_{1}}
\end{aligned}
$$

Unbiased but not consistent (Hendry and Santos (2005)). With variance:

$$
\mathrm{V}[\hat{\gamma}]=\mathrm{V}\left[\epsilon_{\mathrm{T}_{1}}\right]=\sigma_{\epsilon}^{2}
$$

t-statistic:

$$
\mathrm{t}_{\hat{\gamma}}=\frac{\hat{\gamma}}{\hat{\sigma}_{\epsilon}} \approx \frac{\left(\hat{\gamma}-\lambda_{1}\right)}{\sigma_{\epsilon}}+\frac{\lambda_{1}}{\sigma_{\epsilon}} \sim \mathrm{N}\left(\psi_{\lambda_{1}}, 1\right)
$$

Illustrate IIS for a location shift of $\lambda$ over last $k$ observations:

$$
\begin{equation*}
y_{t}=\mu+\lambda 1_{\{\mathrm{t} \geqslant \mathrm{~T}-\mathrm{k}+1\}}+\varepsilon_{\mathrm{t}} \tag{14}
\end{equation*}
$$

where $\varepsilon_{\mathrm{t}} \sim \operatorname{IN}\left[0, \sigma_{\varepsilon}^{2}\right]$ and $\lambda \neq 0$.

Optimal test is t-test for a break in (14) at $\mathrm{T}-\mathrm{k}+1$ onwards, requires:

- knowledge of location-shift timing
- knowing that it is the only break
- is same magnitude break thereafter

The next slide records IIS for $\lambda=10 \sigma_{\varepsilon}$ in (14) at $0.75 \mathrm{~T}=75$.

## Structural break example

- Size of the break is $\mathbf{1 0}$ standard errors at 0.75 T
- There are no outliers in this mis-specified model as all residuals $\in[-2,2]$ SDs:
outliers $\neq$ structural breaks
- step-wise regression has zero power

## 'Split-sample' search in IIS

Institute for

- Initially, many indicators now retained (top row), considerable discrepancy between the first-half and second-half means.
- When second set entered, all indicators for location shift period are retained.
- Once combined set entered, despite large number of dummies, selection reverts to just those for break period.

Under null, indicators significant in sub-sample would remain so overall, for alternatives, sub-sample significance can be transient, due to unmodeled features that occur elsewhere in data.

## IIS and SIS

## Extension of IIS to step-indicator saturation (SIS):

Regression model saturated with complete set of step indicators

$$
\mathcal{S}_{1}=\left\{1_{\{t \leqslant j\}}, j=1, \ldots, T\right\}
$$

where $1_{\{t \leqslant j\}}=1$ for observations up to $j$, and zero otherwise.
Step indicators cumulate impulse indicators up to each next observation:

$$
\begin{array}{cc}
\text { IIS: Impulses } & \text { SIS: Step shifts } \\
{\left[\begin{array}{cccc}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & \ddots
\end{array}\right]} & {\left[\begin{array}{llll}
1 & 1 & 1 & 1 \\
0 & 1 & 1 & 1 \\
0 & 0 & 1 & 1 \\
0 & 0 & 0 & 1
\end{array}\right]}
\end{array}
$$

Step indicators take the form:
$\iota_{1}^{\prime}=(1,0,0, \ldots, 0), \iota_{2}^{\prime}=(1,1,0, \ldots, 0), \ldots, \iota_{\top}^{\prime}=(1,1,1, \ldots, 1)$,

## IIS and SIS

## Extension of IIS to step-indicator saturation (SIS):

Regression model saturated with complete set of step indicators

$$
\mathcal{S}_{1}=\left\{1_{\{t \leqslant j\}}, j=1, \ldots, T\right\}
$$

where $1_{\{t \leqslant j\}}=1$ for observations up to $j$, and zero otherwise.

IIS and SIS - important differences necessitate a new analysis:

- Impulse Indicators: mutually orthogonal. Step indicators overlap increasingly as their second index increases.
- Two indicators are required to characterize an outlier or shift not at the end of the sample: $1_{\left\{\mathrm{t} \leqslant \mathrm{T}_{2}\right\}}-1_{\left\{\mathrm{t}<\mathrm{T}_{1}\right\}}$.
- Opens the door to "designed break functions" (Volcanoes! See Pretis, Schneider, Smerdon, and Hendry (2016))

## Step-indicator saturation

The Step-Indicator Saturation Model (Infeasible as $\mathrm{N} \gg \mathrm{T}$ ):

$$
\begin{equation*}
y_{t}=\beta_{0}+\beta_{1}^{\prime} \mathbf{z}_{\mathrm{t}}+\sum_{j=1}^{\mathrm{T}-1} \delta_{j} 1_{\{\mathrm{t} \leqslant \mathrm{j}\}}+\epsilon_{\mathrm{t}} \text { where } \epsilon_{\mathrm{t}} \sim \operatorname{IN}\left[0, \sigma_{\epsilon}^{2}\right] \tag{15}
\end{equation*}
$$

## Split-Half Approach:

- Add the first $\mathrm{T} / 2$ indicators from the saturating set $\mathcal{S}_{1}$ :

$$
\begin{equation*}
y_{t}=\beta_{0}+\beta_{1}^{\prime} z_{t}+\sum_{j=1}^{\mathrm{T} / 2} \delta_{j} 1_{\{\mathrm{t} \leqslant \mathrm{j}\}}+\epsilon_{\mathrm{t}} \tag{16}
\end{equation*}
$$

can be estimated directly, indicators retained when estimated coefficients $\widehat{\delta}_{j}$ satisfy $\left|t_{\hat{\delta}_{j}}\right|>c_{\alpha}$ where $c_{\alpha}$ is the critical value for significance level $\alpha$.

- Locations are recorded, all those indicators are dropped, second set is then investigated.
- Combine selected indicators and re-select.

## Null rejection frequency of SIS

- Under the null with $\alpha=1 / \mathrm{T}$, at both sub-steps on average, $\alpha \mathrm{T} / 2$ (namely $1 / 2$ an indicator) will be retained by chance.
- On average $\alpha \mathrm{T}=1$ indicator will be retained from the combined stage: gauge should equal nominal size.
- One degree of freedom is lost on average.

When $m$ indicators are selected in a congruent representation at significance level $\alpha$ :

$$
\begin{equation*}
y_{t}=\beta_{0}+\beta_{1}^{\prime} z_{t}+\sum_{i=1}^{m} \phi_{i, \alpha} 1_{\left\{t \leqslant T_{i}\right\}}+v_{t} \tag{17}
\end{equation*}
$$

where $v_{\mathrm{t}} \sim \operatorname{IN}\left[0, \sigma_{v}^{2}\right]$, and coefficients of significant indicators are denoted $\phi_{\mathrm{i}, \alpha}$.

## 'Split-sample’ search by SIS at $1 \%$.

## 'Split-sample’ search by SIS at $1 \%$.

## Illustrating SIS when no location shifts

Institute for

Selected model: actual and fitted

$T=100$, and no shifts, retains 2 significant steps, so lose 2 degrees of freedom-but could be combined to one dummy.

OXFORD
Institute for

## Under the null of no shift:

Model with $n=0$ : using the split-half approach where $\beta_{0}=0$, $\epsilon_{\mathrm{t}} \sim \operatorname{IN}\left[0, \sigma_{\epsilon}^{2}\right]$ and $\sigma_{\epsilon}^{2}=1$, for a sample size $\mathrm{T}=100$ and various values of $\alpha$.

Retention frequency of irrelevant indicators: close to $\alpha$, on average $\alpha \mathrm{T}$ irrelevant step indicators retained under the null:

## Simulating SIS when no location shifts

Institute for

Properties of two out of the 100 step indicators ( $T_{1}=20, T_{2}=35$ ) under the null of no shift:

Density of Estimators (under null)
t -Statistics (under null)

Both estimators $\widehat{\gamma}_{T_{1}}$ and $\widehat{\gamma}_{T_{2}}$ have densities close to Normal, centered on zero, and central t-statistics.

Known mean shift from $\lambda_{1} \neq 0$ to $\lambda_{1}=0$ at time $0<\mathrm{T}_{1}<\mathrm{T} / 2$ in DGP:

$$
\begin{equation*}
y_{\mathrm{t}}=\mu+\lambda_{1} 1_{\left\{\mathrm{t} \leqslant \mathrm{~T}_{1}\right\}}+\epsilon_{\mathrm{t}} \text { where } \epsilon_{\mathrm{t}} \sim \operatorname{IN}\left[0, \sigma_{\epsilon}^{2}\right] \tag{18}
\end{equation*}
$$

where $\lambda_{1} \neq 0$ : shift is from $\mu+\lambda_{1}$ to $\mu$.
Nesting model of (18) when the break is known:

$$
\begin{equation*}
y_{t}=\varphi+\delta_{\mathrm{T}_{1}} 1_{\left\{\mathrm{t} \leqslant \mathrm{~T}_{1}\right\}}+v_{\mathrm{t}} \tag{19}
\end{equation*}
$$

As $\sum_{t=1}^{\mathrm{T}} 1_{\left\{\mathrm{t} \leqslant \mathrm{T}_{1}\right\}}=\sum_{\mathrm{t}=1}^{\mathrm{T}_{1}} 1_{\left\{\mathrm{t} \leqslant \mathrm{T}_{1}\right\}}=\mathrm{T}_{1}$, estimating (19) delivers:

$$
\binom{\widehat{\varphi}-\mu}{\widehat{\delta}_{T_{1}}-\lambda_{1}}=\left(\begin{array}{cc}
T & T_{1} \\
\mathrm{~T}_{1} & T_{1}
\end{array}\right)^{-1}\binom{\sum_{t=1}^{\mathrm{t}=1} \epsilon_{\mathrm{t}}}{\sum_{\mathrm{t}=1}^{\mathrm{T}} \epsilon_{\mathrm{t}}}=\binom{\bar{\epsilon}_{(2)}}{\bar{\epsilon}_{(1)}-\bar{\epsilon}_{(2)}}
$$

where $\bar{\epsilon}_{(1)}=T_{1}^{-1} \sum_{t=1}^{T_{1}} \epsilon_{t}$ average over first $T_{1}$ observations and $\bar{\epsilon}_{(2)}=\left(T-T_{1}\right)^{-1} \sum_{t=T_{1}+1}^{T} \epsilon_{t}$

And the variance is:

$$
\mathrm{V}\left[\binom{\widehat{\varphi}-\mu}{\widehat{\delta}_{T_{1}}-\lambda_{1}}\right]=\sigma_{\epsilon}^{2}\left(\mathrm{~T}-\mathrm{T}_{1}\right)^{-1}\left(\begin{array}{cc}
1 & -1 \\
-1 & \mathrm{~T}_{1}^{-1}\left(\mathrm{~T}-\mathrm{T}_{1}\right)+1
\end{array}\right) .
$$

For the DGP in (18):

$$
\begin{equation*}
\sqrt{\mathrm{T}^{*}}\left(\widehat{\delta}_{\mathrm{T}_{1}}-\lambda_{1}\right) \sim \mathrm{N}\left[0, \sigma_{\epsilon}^{2}\right] \tag{20}
\end{equation*}
$$

Hence, neglecting the estimation uncertainty in $\widehat{\sigma}_{\epsilon}^{2}$ and letting $\left(\mathrm{T}_{1}^{-1}+\left(\mathrm{T}-\mathrm{T}_{1}\right)^{-1}\right)^{-1}=\mathrm{T}^{*}$ :

$$
\begin{equation*}
\mathrm{t}_{\widehat{\delta}_{T_{1}}}=\frac{\sqrt{\mathrm{T}^{*}} \widehat{\delta}_{\mathrm{T}_{1}}}{\widehat{\sigma}_{\epsilon}} \approx \frac{\sqrt{\mathrm{T}^{*}}\left(\widehat{\delta}_{\mathrm{T}_{1}}-\lambda_{1}\right)}{\sigma_{\epsilon}}+\frac{\sqrt{\mathrm{T}^{*}} \lambda_{1}}{\sigma_{\epsilon}} \sim \mathrm{N}\left[\psi_{\lambda_{1}}^{*}, 1\right] \tag{21}
\end{equation*}
$$

where $T^{*}=T_{1}$ when there is no intercept. Yields $\sqrt{T^{*}}$ times the corresponding non-centrality for an individual impulse indicator.

## Illustrating 'split-half' SIS for a single location shift

Institute for
New Economic Thinking
AT THE OXFORD MARTIN SCHOOL

Add half indicators and select ones significant at $1 \%$.

Indicators retained

Selected model: actual and fitted

## Illustrating 'split-half' SIS for a single location shift

AT THE OXFORD MARTIN SCHOOL

## Drop, add other half indicators and again select at $1 \%$.

Selected model: actual and fitted

## Illustrating 'split-half' SIS for a single location shift

OXFORD
MARTIN SCHOOL

Institute for

Combine retained indicators and re-select at $1 \%$.

Matching theory: initially retains last step indicator closest to mean shift, then finds correct shift, so eliminates redundant indicator. Just one step indicator needed.

## Potency for an unknown shift

Detection of single location shift falling within a half-sample of the data ( $0<\mathrm{T}_{1}<\mathrm{T} / 2$ ) using split-half analysis of SIS where DGP is:

$$
\begin{equation*}
\mathbf{y}=\lambda_{1} \iota_{T_{1}}+\epsilon \tag{22}
\end{equation*}
$$

Add first half of step indicators, model is:

$$
\begin{equation*}
y_{t}=\sum_{j=1}^{\mathrm{T} / 2} \gamma_{j} 1_{\{t \leqslant j\}}+v_{t} \tag{23}
\end{equation*}
$$

Intercept of zero highlights main aspects of the algebra, written as:

$$
\begin{equation*}
\mathbf{y}=\mathbf{D}_{1} \gamma_{(1)}+\mathbf{v} \tag{24}
\end{equation*}
$$

where $\gamma_{(1)}=\left(\gamma_{1} \ldots \gamma_{\mathrm{T} / 2}\right)^{\prime}$ and $\mathbf{D}_{1}=\left(\iota_{1} \ldots \iota_{\mathrm{T} / 2}\right)$. Then:

$$
\begin{equation*}
\widehat{\gamma}_{(1)}=\left(\mathbf{D}_{1}^{\prime} \mathbf{D}_{1}\right)^{-1} \mathbf{D}_{1}^{\prime} \mathbf{y}=\lambda\left(\mathbf{D}_{1}^{\prime} \mathbf{D}_{1}\right)^{-1} \mathbf{D}_{1}^{\prime} \iota \mathrm{T}_{1}+\left(\mathbf{D}_{1}^{\prime} \mathbf{D}_{1}\right)^{-1} \mathbf{D}_{1}^{\prime} \boldsymbol{\epsilon} \tag{25}
\end{equation*}
$$

## Properties following from $\mathrm{D}_{1}$

Institute for
New Economic Thinking
The inverse of $\left(\mathbf{D}_{1}^{\prime} \mathbf{D}_{1}\right)$ is the 'double difference' matrix:

$$
\left(\mathbf{D}_{1}^{\prime} \mathbf{D}_{1}\right)^{-1}=\left(\begin{array}{cccccc}
2 & -1 & 0 & \ldots & 0 & 0  \tag{26}\\
-1 & 2 & -1 & \ldots & 0 & 0 \\
0 & -1 & 2 & \ldots & 0 & 0 \\
\vdots & \ddots & \ddots & \ddots & \ddots & \vdots \\
0 & 0 & 0 & \ldots & 2 & -1 \\
0 & 0 & 0 & \ldots & -1 & 1
\end{array}\right)
$$

so:

$$
\left(\mathbf{D}_{1}^{\prime} \mathbf{D}_{1}\right)^{-1} \mathbf{D}_{1}^{\prime}=\left(\begin{array}{cccccc}
1 & -1 & 0 & \ldots & 0 & 0 \\
0 & 1 & -1 & \ldots & 0 & 0 \\
0 & 0 & 1 & \ldots & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \ddots & \vdots \\
0 & 0 & 0 & \ldots & 1 & -1 \\
0 & 0 & 0 & \ldots & 0 & 1
\end{array}\right)
$$

is the forward-difference matrix.

## Split-half for an unknown shift

Letting $\nabla \epsilon_{\mathrm{t}}=\epsilon_{\mathrm{t}}-\epsilon_{\mathrm{t}+1}$, from $\widehat{\gamma}_{(1)}=\left(\mathbf{D}_{1}^{\prime} \mathbf{D}_{1}\right)^{-1} \mathbf{D}_{1}^{\prime} \mathbf{y}$ :

$$
\widehat{\gamma}_{(1)}=\lambda_{1} \mathbf{r}+\nabla \boldsymbol{\epsilon}_{(1)}
$$

where r is a $\mathrm{T} / 2 \times 1$ vector with unity at $\mathrm{t}=\mathrm{T}_{1}$ and zeroes elsewhere, so:

$$
\begin{equation*}
\left(\widehat{\gamma}_{(1)}-\lambda_{1} \mathbf{r}\right)=\nabla \epsilon_{(1)} \tag{27}
\end{equation*}
$$

where the $(\mathrm{T} / 2 \times 1)$ vector $\nabla \epsilon_{(1)}=\left(\nabla \epsilon_{1}, \nabla \epsilon_{2}, \ldots, \nabla \epsilon_{\mathrm{T} / 2}, \epsilon_{\mathrm{T} / 2}\right)^{\prime}$.
All elements of $\widehat{\gamma}_{(1)}$ up to the $T_{1}$ th are zero, only the $T_{1}$ th reflect $\lambda_{1}$, corresponding to the location shift.

Only the value of $\lambda_{1}$ at the shift is being picked up, incremental information equivalent to an impulse indicator for $T_{1}$ :

$$
\begin{equation*}
\widehat{\gamma}_{\mathrm{T}_{1}}=\lambda_{1}+\nabla \epsilon_{\mathrm{T}_{1}} \tag{28}
\end{equation*}
$$

## Low potency if no selection

Hence:

$$
\begin{equation*}
\left(\widehat{\gamma}_{(1)}-\lambda_{1} \mathbf{r}\right)_{\widetilde{\mathrm{app}}} \mathrm{~N}\left[\mathbf{0}, \sigma_{\epsilon}^{2}\left(\mathbf{D}_{1}^{\prime} \mathbf{D}_{1}\right)^{-1}\right] \tag{29}
\end{equation*}
$$

The estimated error variance adjusted for degrees of freedom:

$$
\widehat{\sigma}_{\epsilon}^{2}=\frac{2}{T} \sum_{t=T / 2+1}^{T}\left(y_{t}-\widehat{y}_{t}\right)^{2}
$$

will be an unbiased estimator of $\sigma_{\epsilon}^{2}$. However, for IID errors (because of $\nabla \epsilon_{\mathrm{T}_{1}}$ ):

$$
\begin{equation*}
\mathrm{V}\left[\widehat{\gamma}_{\mathrm{T}_{1}}\right]=2 \sigma_{\epsilon}^{2} \tag{30}
\end{equation*}
$$

so that:

$$
\begin{equation*}
\mathrm{t}_{\hat{\gamma}_{\mathrm{T}_{1}}}=\frac{\widehat{\gamma}_{\mathrm{T}_{1}}}{\sqrt{2} \widehat{\sigma}_{\epsilon}} \approx \frac{\left(\widehat{\gamma}_{\mathrm{T}_{1}}-\lambda_{1}\right)}{\sqrt{2} \sigma_{\epsilon}}+\frac{\lambda_{1}}{\sqrt{2} \sigma_{\epsilon}} \sim \mathrm{N}\left[\frac{\psi_{\lambda_{1}}}{\sqrt{2}}, 1\right] \tag{31}
\end{equation*}
$$

where $\psi_{\lambda_{1}} / \sqrt{2}$ is the non-centrality. Note: indep. of length of shift.
$\mathrm{V}\left[\widehat{\gamma}_{\mathrm{T}_{1}}\right]=2 \sigma_{\epsilon}^{2}$ due to collinearity between step indicators:
Eliminating insignificant indicators by sequential selection or multi-path search is essential.

Example: At $1 \%, \mathrm{c}_{\alpha} \approx 2.7$, normalizing on $\sigma_{\epsilon}=1$, requires $\lambda_{1}>3.8$ for even a $50 \%$ chance of significance before simplification.

When insignificant indicators are deleted, $\mathrm{V}\left[\widehat{\gamma}_{\mathrm{T}_{1}}\right]$ falls rapidly:
If all irrelevant indicators eliminated, just $\iota \mathrm{T}_{1}$ remains, the non-centrality for a single shift $\psi_{1}=\sqrt{\mathrm{T}^{*}} \lambda_{1} / \sigma_{\epsilon}$ which is $\sqrt{2 \mathrm{~T}^{*}}$ larger than before selection.

## Second half

First half step indicators are then eliminated and second half, $\mathbf{D}_{2}=\left(\iota_{\mathrm{T} / 2+1} \cdots \iota_{\mathrm{T}}\right)$ added.

- If significant steps from first half retained: only $\alpha / 2$ of estimated coefficients of $\mathbf{D}_{2}$ should be significant
- If significant steps are not retained then model becomes:

$$
\begin{equation*}
y_{t}=\sum_{j=T / 2+1}^{T} \gamma_{j} 1_{\{\mathrm{t} \leqslant \mathrm{j}\}}+v_{\mathrm{t}} \tag{32}
\end{equation*}
$$

written as:

$$
\begin{equation*}
\mathbf{y}=\mathbf{D}_{2} \gamma_{(2)}+\mathbf{v} \tag{33}
\end{equation*}
$$

where $\gamma_{(2)}=\left(\gamma_{\mathrm{T} / 2+1} \ldots \gamma_{\mathrm{T}}\right)^{\prime}$ and $\mathbf{D}_{2}=\left(\iota_{\mathrm{T} / 2+1} \ldots \iota_{\mathrm{T}}\right)$. From (22):

$$
\begin{equation*}
\widehat{\gamma}_{(2)}=\left(\mathbf{D}_{2}^{\prime} \mathbf{D}_{2}\right)^{-1} \mathbf{D}_{2}^{\prime} \mathbf{y}=\lambda_{1}\left(\mathbf{D}_{2}^{\prime} \mathbf{D}_{2}\right)^{-1} \mathbf{D}_{2}^{\prime} \iota \mathrm{T}_{1}+\left(\mathbf{D}_{2}^{\prime} \mathbf{D}_{2}\right)^{-1} \mathbf{D}_{2}^{\prime} \boldsymbol{\epsilon} \tag{34}
\end{equation*}
$$

$$
\left(\mathbf{D}_{2}^{\prime} \mathbf{D}_{2}\right)=\left(\mathbf{D}_{1}^{\prime} \mathbf{D}_{1}\right)+\frac{1}{2} T \mathbf{c c}^{\prime}
$$

where $\mathbf{c}$ is a $\mathrm{T} / 2 \times 1$ vector of ones and j is a $\mathrm{T} / 2 \times 1$ vector of zeroes other than unity at first element:

$$
\left(\mathbf{D}_{2}^{\prime} \mathbf{D}_{2}\right)^{-1}=\left(\mathbf{I}_{\mathrm{T} / 2}+\frac{\mathrm{T}}{2} \mathbf{j} \mathbf{c}^{\prime}\right)^{-1}\left(\mathbf{D}_{1}^{\prime} \mathbf{D}_{1}\right)^{-1}
$$

and:

$$
\begin{equation*}
\widehat{\gamma}_{(2)}=\lambda_{1} \mathrm{~T}_{1}\left(\mathbf{I}_{\mathrm{T} / 2}+\frac{\mathrm{T}}{2} \mathbf{j} \mathbf{c}^{\prime}\right)^{-1} \mathbf{j}+\left(\mathbf{D}_{2}^{\prime} \mathbf{D}_{2}\right)^{-1} \mathbf{D}_{2}^{\prime} \boldsymbol{\epsilon} \tag{35}
\end{equation*}
$$

- Only first element of $\widehat{\gamma}_{(2)}$ depends on $\lambda_{1}$ : indicator nearest to shift retained if relevant indicators not 'carried forward'.

Finally, combine selected step indicators and re-select. When all irrelevant indicators are removed and the relevant one retained:

$$
\begin{equation*}
y_{\mathrm{t}}=\gamma_{\mathrm{T}_{1}} 1_{\left\{\mathrm{t} \leqslant \mathrm{~T}_{1}\right\}}+v_{\mathrm{t}} \tag{36}
\end{equation*}
$$

perfect selection coincides with DGP; retained irrelevant indicators reduce degrees of freedom, and increase variances.

## Simulating SIS for a single location shift

Location Shift at $T_{1}=35$, magnitude $\lambda_{1}=4 \sigma_{\epsilon}$, selection at $\alpha=0.01$.

Sequential selection (grey) reduces variance vs. split-half (open, blue).

Exact ( $\hat{T}_{1}=T_{1}$ ) retention frequency of break for alternative methods, varying break lengths $l$ and magnitudes, $\lambda_{1}$

## Mis-selected indicator

Institute for
New Economic Thinking
AT THE OXFORD MARTIN SCHOOL
Selected step indicators may not exactly match location shift Random draws of error: Mis-timed break indicator for shift at $t=25$ :

## Mis-timing of selected indicators

SIS selection can 'miss' by periods. Low potency primarily due to mis-timing rather than not detecting the shift:

Even for $\lambda=2 \sigma_{\epsilon}$ and short breaks, potency is 0.9 or higher by $\mathrm{T}_{1} \pm 3$.

## Generalization to retained regressors

Simulate SIS with $n<$ T general regressors, with single step shift with unknown timing requiring two indicators, the DGP is:

$$
\begin{equation*}
y_{t}=\beta_{1}^{\prime} \mathbf{z}_{\mathrm{t}}+\lambda_{1}\left(1_{\left\{\mathrm{t} \leqslant \mathrm{~T}_{2}\right\}}-1_{\left\{\mathrm{t} \leqslant \mathrm{~T}_{1}\right\}}\right)+\epsilon_{\mathrm{t}} \text { where } \epsilon_{\mathrm{t}} \sim \operatorname{IN}\left[0, \sigma_{\epsilon}^{2}\right] \tag{37}
\end{equation*}
$$

Even including 10 relevant regressors (not selected over), densities of the two shift estimators, $\widehat{\gamma}_{i}$, centered around true value $\lambda_{1}=4 \sigma_{\epsilon}$ :

Step-Indicator Saturation with general regressors for a 4SD step shift

Potency unaffected by regressors ( $\approx 0.5$ for 2SD, $\approx 0.9$ for 4SD)

## Implementation

- Step and Impulse-Indicator Saturation (SIS, IIS) in PcGive/Ox
- isat in in $R$-package 'get s' (Pretis et al. 2016) (with Genaro Sucarrat and James Reade)
- Note: SIS construction differs between PcGive \& R
- PcGive: $\mathrm{d}_{\mathrm{T}_{1}}=1_{\left\{t \leqslant \mathrm{~T}_{1}\right\}}, \hat{\gamma}>0$ implies negative shift.
- $\mathrm{R}: \mathrm{d}_{\mathrm{T}_{1}}=1_{\left\{\mathrm{t} \geqslant \mathrm{T}_{1}\right\}}, \hat{\gamma}>0$ implies positive shift.

## SIS in PcGive/Ox:

Model Settings - Single-equation Dynamic Modelling

## Choose a model type:

Ordinary least squares
Choose the Autometrics options:
Automatic model selection

## 回

Outlier and break detection Step indicator saturation (SIS)

SIS in R: isat (gets)

```
isat(y, mxreg=..., ar=1:2,
    sis=TRUE, iis=FALSE, t.pval=0.005,...)
```

model.Autometrics(0.001, "SIS", ...);

## Application: Sea Surface Temperature

Institute for
New Economic Thinking
Global SST - Climate/Weather Indicator Shape of trend? Breaks in series? El Niño Southern Oscillation?

## SST: Model Setup

## Model:

$$
\begin{equation*}
\mathbf{y}_{\mathbf{t}}=\mathbf{f}\left(\mathbf{z}_{\mathbf{t}}\right)+\beta \mathbf{x}_{\mathbf{t}}+\delta \mathbf{D}+\epsilon_{\mathrm{t}} \tag{38}
\end{equation*}
$$

- T=108 (1900-2008)
- $\mathbf{y}=$ Global Mean SST Anomalies (C) relative to 1950-79
- $\mathbf{z = t}, \mathbf{x}=$ Southern Oscillation Index (SOI) (atm. pressure at SL)
- $\mathbf{N}=108+6=114$ variables

## Specification:

- SIS, $p_{\alpha}=0.001$ (0.1\%)
- Nonlinear trend: B-spline basis (5 degree polynomial)

## SST: SIS Results (Fitted)

Two breaks: 1941, $\hat{\delta}_{1}=0.43^{* * *} \mathrm{C}(\mathrm{se}=0.046)$
1946, $\hat{\delta}_{2}=-0.24^{* * *} \mathrm{C}(\mathrm{se}=0.048)$

## SST: Interpreting the structural break

- WWII: 1941/1942 Measurements: buckets to engine intake
- Danger of measurements (light)
- Americans joined 1941/1942
- Post-WWII: Partly changed back

## SST: Interpreting the structural break

- WWII: 1941/1942 Measurements: buckets to engine intake
- Danger of measurements (light)
- Americans joined 1941/1942
- Post-WWII: Partly changed back
- Buckets: cold bias ( $\approx 0.3 \mathrm{C}$ ) (Matthews, 2012)
- SIS: $\hat{\delta}_{1}=0.43( \pm 0.046)$

## SST: Linear \& Break Component

## SOI Effect (linear)

- SIS: $\hat{\beta}=-0.004^{* * *}$ (se=0.001)
- Theory consistent: SOI > 0 (La Niña) $\rightarrow$ lower temp. (hiatus?!)

## Breaks

- Correct SST record for 'bucket bias'

Commence with general formulation - general unrestricted model:

$$
y_{t}=\boldsymbol{\beta}^{\prime} \mathbf{z}_{\mathrm{t}}+\gamma^{\prime} \mathbf{w}_{\mathrm{t}}+\sum_{j=1}^{\mathrm{T}} \delta_{\| I S, j} \mathbf{1}_{\{j=\mathrm{t}\}}+\sum_{j=1}^{\mathrm{T}-1} \delta_{\mathrm{SIS}, \mathrm{j}} \mathbf{1}_{\{j \leqslant \mathrm{t}\}}+v_{\mathrm{t}} \quad \mathrm{t}=1, \ldots, \mathrm{~T}
$$

- Embed theory $z_{\mathrm{t}}$
- Expand model $w_{\mathrm{t}}$ (almost costless if theory correct)
- Indicators $\delta_{\mathrm{t}}$ (almost costless under null)
- Ensuring valid conditioning - exogeneity
